

SOLUTION 1

SOLUTIONS - 2008

S011

C5-23

The code $\text{Ham}(3)$ has as its check matrix the 3×7 matrix whose columns are all possible non-zero binary triples. Hence it has block length 7, rank 4, and since it can correct all single errors minimum distance at least 3. Since there are code words of weight 3, that is the precise minimum distance.

Adding a check bit increases the block length to 8, and it leaves the rank unchanged (as the number of code words is unchanged). Since a word of weight 3 becomes a word of weight 4, the minimum distance goes up to 4.

The zero word and the all 1s word are code words of $\text{Ham}(3)$ and hence the same holds for the extended zero and all 1s word. Any other word of the code must have at least 4 1s (so that its distance from $\underline{0}$ is 4 and at least 4 zeros so that its distance from the all 1s word is at least 4. Thus it must have exactly 4 1s.

As every codeword has even weight by construction it follows immediately that $u \cdot u = 0$. It also follows immediately that for any code word $u \neq \underline{0}, \underline{1}$ both $u \cdot \underline{0}$ and $u \cdot \underline{1}$ are 0 (the first is the sum of 8 0s and the second is the sum of 4 1s and 4 0s). Now suppose that both u and $v \neq u$ have weight 4. They must differ in four places because their difference is a code word $\neq \underline{0}, \underline{1}$. Since they both have weight 4 the number of 1s in u corresponding to 0s in v must be exactly equal to the number of 0s in u corresponding to 1s in v . Hence exactly two 1s of u become 0s in v . Thus $u \cdot v$ is the sum of two 1s which is 0.

Now let G be any generator matrix and let $H = G^\top$. the rows of H are code words of C and by the argument we have just given it follows that $Hv = \underline{0}$ for all $v \in C$. So C is contained in the code C' with check matrix H , but by the theorem $\text{rank } C' = 4 = \text{rank } C$ and so the codes must be equal.

SOLUTION 2

A code is r -perfect if every received word lies with Hamming distance r of exactly one code word.

The code $\text{Ham}(k)$ has as its check matrix a binary $k \times 2^k - 1$ matrix whose columns are all non-zero binary k -tuples, each occurring once. A received word has syndrome $\underline{0}$ or its syndrome is equal to a unique column of the check matrix. In the first case it is a code word. In the second changing the bit corresponding to the column equal to its syndrome produces a code word. Changing any other bit adds the corresponding column to the syndrome, which therefore does not become $\underline{0}$. That means it does not produce a code word. Thus every non-code word is at distance 1 from a unique code word and $\text{Ham}(k)$ is perfect.

For block length 8 the number $N_1 = 1 + 8 = 9$. If a code C of block length 8 can correct single errors, then the disks of Hamming radius 1 around code words must be disjoint. So

$$|C| \cdot 9 \leq 2^8 = 256.$$

Hence $|C| \leq 256/9 < 29$. Thus $|C| \leq 28$.

The disks of radius 1, 2 and 3 about code words of block length 8 contain 9, $9 + 4 \times 7 = 37$ and $37 + 4 \times 7 \times 2 = 93$ words. None of these numbers exactly divide 256 and therefore there cannot be r -perfect codes for $r = 1, 2, 3$. The greatest possible distance between words in \mathbb{B}^8 is 8 and so disks of radius ≥ 4 cannot be disjoint. Therefore there are no r -perfect codes for $r \geq 4$.

If $\text{BCH}(4,3)$ were r -perfect, r would have to be at least 3. Let N_r denote the number of words at distance at most r from a code word. For an r -perfect binary linear code C of block length 15 we must have $|C| N_r = 2^{15}$ and if the code has rank m , then $|C| = 2^m$. Hence N_r must be 2^{15-m} . Now

$$N_r = 1 + 15 + \binom{15}{2} + \cdots + \binom{15}{r}. \quad (*)$$

Calculating this value for successive values of r starting with $r = 3$ we get

$$N_3 = 576, N_4 = 1941, N_5 = 4946, \dots$$

None of these are powers of 2, and the last is greater than $2^{15-3} = 2^{12}$. Therefore $\text{BCH}(4,3)$ cannot be perfect.

SOLUTION 3

The characteristic of a finite field is the smallest number of times that 1 must be added to itself to produce 0. We denote the sum of n copies of 1 by $n \circ 1$. The distributive law implies that $(m \circ 1)(n \circ 1) = (mn) \circ 1$. Let p be the smallest positive number such that $p \circ 1 = 0$. If $p = mn$ with $m, n < p$ then $0 = (m \circ 1)(n \circ 1)$, so one of $m \circ 1$ and $n \circ 1$ must be zero, contradicting the minimality of p . Hence p has no proper factors and is prime.

First note that $p \cdot a = (p \cdot 1)a = 0 \cdot a = 0$. Next, observe that the binomial theorem allows us to calculate $(a + b)^p$:

$$(a + b)^p = \binom{p}{0} a^p + \binom{p}{1} a^{p-1} b + \cdots + \binom{p}{p} b^p.$$

But the formula $\binom{p}{k} = p!/(k!(p-k)!)$ shows that for $k \neq 0, p$, $\binom{p}{k}$ is a multiple of p . So all the middle terms of the expansion are 0. Hence $(a + b)^p = a^p + b^p$.

Suppose that $x^p = y^p = a$. Then $x^p - y^p = 0$. If the characteristic p is odd, then $-y^p = (-y)^p$. If it is 2, then $-y^p = y^p = (-y)^p$. In either case we have $x^p + (-y)^p = 0$. Hence $(x + (-y))^p = 0$ and so $x - y = 0$ or $x = y$. Thus a has at most one p th root.

Consider the p th powers of the elements of F . By what has been just shown they are all distinct and there are exactly $|F|$ of them, hence every element of F must occur as a p th power and so they all have p th roots.

Since square roots are unique and exist, there is exactly one fourth root of any field element in $\text{GF}(256)$. We need to find n so that $4n \equiv 7 \pmod{255}$. The unique answer is $n \equiv 193 \pmod{255}$, which can be found by trial and error or using Euclid's algorithm.

SOLUTION 4

F is a vector space over its prime field \mathbb{B} . If F is finite, then the dimension of this space must be finite. Now every vector in a vector space of dimension n over the field \mathbb{B} can be represented by a coordinate sequence (x_1, \dots, x_n) and every such sequence determines a unique vector. So the number of vectors is the same as the number of coordinate sequences. We know \mathbb{B} has 2 elements. So there are exactly 2^n coordinate sequences (x_1, \dots, x_n) with entries in \mathbb{B} .

It is possible to solve the second part using a book work criterion involving the derivative of the polynomial. Here is a neater direct solution.

Let α be a root of $x^q - x$. Then $(x - \alpha)^q = x^q - \alpha^q = x^q - \alpha$ since q is a power of the characteristic 2. Thus

$$\begin{aligned}x^q - x &= (x^q - \alpha) - (x - \alpha) \\&= (x - \alpha)^q - (x - \alpha) \\&= (x - \alpha)((x - \alpha)^{q-1} - 1).\end{aligned}$$

Since α does not divide the second term, it is not a multiple root of $x^q - x$.

By the second part there are exactly q roots, so the number of elements is correct. We must show that the set of roots is closed under addition, multiplication, and taking inverses (negatives is unnecessary in characteristic 2). If $\alpha^q = \alpha$ and $\beta^q = \beta$ then $(\alpha\beta)^q = \alpha^q\beta^q = \alpha\beta$ and $(\alpha^{-1})^q = (\alpha^q)^{-1} = \alpha^{-1}$. For addition we use the result of question 3 and find that $(\alpha + \beta)^q = \alpha^q + \beta^q = \alpha + \beta$. So closure holds and the set forms a field.

The roots of $x^4 - x$ in $\text{GF}(16)$ are 0, 1, 10, 11 (by inspection). So by the previous result, they form a field of order 4.

SOLUTION 5

Received Word: 1 2 1 1 2 1 1 2 1 1 2 1 6 8 7

Syndrome Calculation:

Error Evaluator/ x : 1 1 8

Evaluated: 2: 14, 4: 5, 8: 15

Derivative of Error Locator: 2: 3, 4: 2, 8: 6

Error Values: 13 14 14

Corrected Word: 12 12 15 1 2 1 1 2 1 1 2 1 6 8 7

SOLUTION 6

Transmitted Codeword	:	$c(x) = c_m x^m + \dots + c_0$
Received Word	:	$d(x) = d_m x^m + \dots + d_0$
Error Word	:	$d(x) - c(x) = e(x) = e_m x^m + \dots + e_0$
Error Positions	:	$M = \{i : e_i \neq 0\},$
	:	$s = M \leq t$
Error Locator Polynomial	:	$l(z) = \prod_{i \in M} (1 - \alpha^i z)$
This has roots	:	$\{\alpha^{-i} : i \in M\}$
Error Evaluator Polynomial	:	$w(z) = \sum_{i \in M} e_i \alpha^i \prod_{j \in M \setminus i} (1 - \alpha^j z)$
Syndromes	:	$d(\alpha^i) = e(\alpha^i) = S_i \text{ for } i = 1, \dots, 2t$
Syndrome Polynomial	:	$s(z) = \sum_{i=1}^{2t} S_i z^{i-1}$
Fundamental Equation	:	$l(z)s(z) \equiv w(z) \pmod{z^{2t}}.$

Error Pattern: 1 0 0 0 0 1 0 0 0 0 1 0 0 0 0. Syndrome Calculation:

	1	0	0	0	0	1	0	0	0	0	1	0	0	0	0
2:	1	2	4	8	9	10	13	3	6	12	0	0	0	0	0
8:	1	8	15	5	3	0	0	0	0	0	1	8	15	5	3
11:	1	11	10	1	11	11	10	1	11	10	0	0	0	0	0

Thus $S_1 = 0$ and so $S_2 = S_4 = 0$. $S_3 = 3$ and so $S_6 = 3^2 = 5$, $S_5 = 0$.
 Syndrome Polynomial: $s(z) = 5z^5 + 3z^2$. The error locations are 14, 9 and 4.
 Hence the error locator is

$$(1 - 14z)(1 - 9z)(1 - 4z) = 3z^3 + 1.$$

The error evaluator is

$$14(1 - 9z)(1 - 4z) + 9(1 - 14z)(1 - 4z) + 4(1 - 14z)(1 - 9z) = 3z^2$$

Verifying the fundamental equation gives:

$$l(z)s(z) = (3z^3 + 1)(5z^5 + 3z^2) = 15z^8 + 3z^2 \equiv w(z) \pmod{z^6}.$$

Received word: 1 0 1 1 0 1 1 0 1 1 0 1 1 0 1.
 Syndrome calculation:

	1	0	1	1	0	1	1	0	1	1	0	1	1	0	1
2:	1	2	5	11	15	6	13	3	7	15	7	15	6	12	0
8:	1	8	14	12	4	10	7	10	7	11	14	12	5	3	0
11:	1	11	11	11	10	0	1	11	11	11	10	0	1	11	11

The syndrome polynomial is $s(z) = 11z^4$. This divides z^6 and $l(z)s(z)$ will be a multiple of z^4 for any polynomial $l(z)$. So it is impossible for the fundamental equation to hold. Hence there must be more than 3 errors.
